

QA Checklist and Bug Tracking Report

dev-portfolio, Eduard Rotaru

Assignment 2: QA Testing and Bug Tracking

Overview

This document is my QA checklist for testing my portfolio site. I built it myself for this project, covering my portfolio's core requirements, browser support, code optimization, CMS and backend support, metadata, and content accuracy and quality. I used this checklist to test my site and found issues, which I logged as GitHub Issues, fixed, and commented on with how each one was resolved. My instructor, Airrick Dunfield, has been added as a collaborator on the repository and assigned to 10 of these issues to retest.

Issue Tracker

Platform used: GitHub Issues

<https://github.com/nobz226/dev-portfolio/issues>

QA Checklist

Below is the full checklist I used to test the site, broken down by category. Each line is something specific I could actually check and mark as pass or fail, rather than a vague goal.

1. Portfolio Requirements and Core Functionality

- Every nav link (Home, About, Projects, Contact) goes to the right page with no console errors.
- Clicking the logo returns to the homepage from every page.
- Every project card on the Projects page links to a working project detail page.
- The previous and next project navigation on a project page moves correctly and hides or disables itself at the first and last project.
- Going to a page that does not exist shows a real 404 page instead of a blank screen.
- The contact form actually sends an email and the message is received, not just a success message on screen.
- The contact form shows a clear error message if the send fails.
- All outside links, including GitHub repo links and live demo links, actually open and go to the right place.
- Any resume or downloadable file opens the correct and current version.
- The mobile menu opens, keeps focus inside it, and closes with escape, an outside click, or picking a link.

2. Browser and Device Support

- Full walkthrough on the latest Chrome, Firefox, Safari, and Edge.
- Check Safari specifically for rendering issues with fonts, gaps, or blur effects.
- Test the 3D model viewer in a browser without WebGL support and confirm there is a usable fallback instead of a blank box.
- Confirm the favicon still shows up correctly in browsers that do not support SVG icons.
- Test at common screen sizes: phone, tablet, small laptop, and full desktop.
- Test the site at 150 percent and 200 percent browser zoom to check for broken layouts.
- Test the homepage and contact form with a screen reader.
- View the page source (not the browser inspector) to confirm metadata tags show up without needing JavaScript to run first.
- Test on a slow connection to make sure loading states appear and nothing breaks.

3. Code Optimization

- Run Lighthouse on mobile and desktop and record the performance, accessibility, best practices, and SEO scores.
- Check the production build output for any unexpectedly large files.
- Look for hardcoded pixel values or layout hacks that were only tuned for one specific case.
- Check for duplicate or conflicting settings across config files such as ESLint, Vite, and Tailwind.
- Confirm every effect that sets up a listener, observer, or timer also cleans it up properly.
- Confirm images use lazy loading where it makes sense and are not oversized.
- Look for unused code, unused CSS classes, and unused packages in package.json.
- Make sure no leftover console logs or debug statements ship in the production build.

4. CMS and Backend Support

- Confirm the contact form's Formspree endpoint is set through an environment variable and that this is documented somewhere, like an example env file.
- Confirm the site fails gracefully with a clear message, not a crash, if that environment variable is missing.
- Confirm any outside service or embed, like the 3D viewer, still degrades gracefully if that service is unavailable.
- Confirm the deployment configuration correctly handles routing for every page, including dynamic project pages, on a full page refresh.

5. Metadata

- Confirm every page has its own accurate title tag, checked in the actual page source and not just the browser inspector.
- Confirm the Open Graph title, description, image, and URL tags appear in the raw HTML response for every page.

- Confirm Twitter card tags appear in the raw HTML as well.
- Test how a link preview actually looks by pasting page URLs into apps like Slack, Discord, or a text message.
- Confirm the canonical URL is correct for each page instead of every page pointing back to the homepage.
- Confirm every URL listed in the sitemap loads correctly and that any images referenced in it actually exist.
- Confirm robots.txt is not accidentally blocking pages that should be searchable.

6. Content Accuracy and Quality

- Proofread all writing on the site for typos, grammar mistakes, and awkward wording.
- Confirm dates, like the copyright year and project dates, are current and correct.
- Confirm each project's listed tech stack actually matches what was used in that project's repo.
- Check color contrast for every piece of text against its background, including text meant to look inactive or dimmed.
- Confirm decorative images are hidden from screen readers, but meaningful images, like a profile photo, are never hidden.
- Confirm animated or typed text does not overlap or create confusing visual noise when several pieces animate at once.
- Confirm all alt text is accurate and descriptive, not left blank or generic when it should describe something meaningful.
- Read through all project descriptions to check that the tone stays consistent and the facts line up with the actual linked repositories.

Issues Found, Fixed, and Assigned for Retest

Running through the checklist above, I found and logged issues in the codebase as detailed bug reports on GitHub, each with steps to reproduce, expected versus actual results, and supporting evidence. The 10 issues below are the ones assigned to my instructor, Airrick Dunfield, for retesting. Each one has already been fixed and commented on with an explanation of how it was resolved. They currently show as open on GitHub because they are waiting on my instructor's retest before being closed out.

Issue #	Bug	Category	Status
#1	Cal Sans font fails to load from Google Fonts	Font Loading / Visual	Fixed, pending retest
#2	Color contrast failures on navigation and footer text	Accessibility	Fixed, pending retest
#3	Contact form inputs missing autocomplete attributes	Accessibility / Forms	Fixed, pending retest
#4	Accordion uses pb-[800px] hack to contain expanded content	Code Quality	Fixed, pending retest
#5	OG image paths are relative instead of absolute	Metadata / SEO / Social Sharing	Fixed, pending retest
#6	renderParagraphs hardcodes text-snow/80 for all section variants	Content / Visual	Fixed, pending retest

Issue #	Bug	Category	Status
#7	Twitter/X handle doesn't match any profile link on site	Content / Metadata	Fixed, pending retest
#8	Duplicate description meta tags in the DOM	Metadata / SEO	Fixed, pending retest
#9	CoreValues renders invisible placeholder causing layout churn	Performance / About Page	Fixed, pending retest
#12	Project filter tags not sorted alphabetically	UI/UX / Projects	Fixed, pending retest

Summary

In total, this checklist covers portfolio requirements, browser support, code optimization, CMS and backend support, metadata, and content accuracy and quality, as required by the assignment. The 10 issues assigned to Airrick Dunfield were logged, fixed, and commented on individually in GitHub Issues, and he now has collaborator access and is assigned to retest each one.
